I'm looking forward to fixing my treadmill tomorrow and discussing our strategies. I purchased this treadmill for my kids and wife, but unfortunately, it was only used for casual walking. Although it performed adequately for short periods of use, its reliability was limited. After a while, the system would shut down, prompting me to switch to an exercise bike. Now that I've got some experience, I'd like to attempt to fix this treadmill myself. My concern is whether the belt's premature failure could be caused by other factors or if it's solely due to a faulty controller board. Unlike a motor, which may gradually deteriorate over time, I'm not convinced that a controller board will either work perfectly or fail completely. If there are alternative components involved in this issue, I'd like to explore those options before replacing just the board to avoid potentially shortening its lifespan.
